## Introduction

Inland lakes and reservoirs are major contributors to the global carbon cycle. It is important to understand how much carbon they emit as well as any significant changes in carbon emissions. Eddy covariance flux tower located in the Ross Barnett Reservoir (RBR) in Ridgeland, MS was used to measure carbon dioxide (CO<sub>2</sub>) concentrations, CO<sub>2</sub> fluxes, and components of the surface energy budget.

Table 1: Instruments at the tower site

Instrument Name	Instrument Heights (m)
CSAT3 3-D sonic anemometer	2.8
LI-7500 CO <sub>2</sub> /H <sub>2</sub> O IR gas analyzer	2.8
CRN 2 net radiometer	1.5
HMP45C Temperature & RH Probe	1.2, 2.4, 2.8, 3.5, 4.7
IRR-P Water skin Temperature sensor	1.5

## Objectives

- Understand CO<sub>2</sub> diurnal patterns and determine what factors influence concentrations.
- Determine if seasonal change in weather variables impacts CO<sub>2</sub> concentration and flux.

## Methods

Data that the RBR flux tower had collected in 2008 were analyzed from June 4<sup>th</sup> to June 18<sup>th</sup>, Nov. 18<sup>th</sup> to Nov. 24<sup>th</sup>, and Dec 1<sup>st</sup> to Dec. 7<sup>th</sup>. An LI-7500 infrared open-path gas analyzer measured CO<sub>2</sub> concentrations and flux. 30 minute averages of CO<sub>2</sub> concentrations were compared with flux data and other meteorological variables, including temperature, net radiation, water surface temperature and wind speed. A CR5000 data logger was used to store data from the tower.

## Results

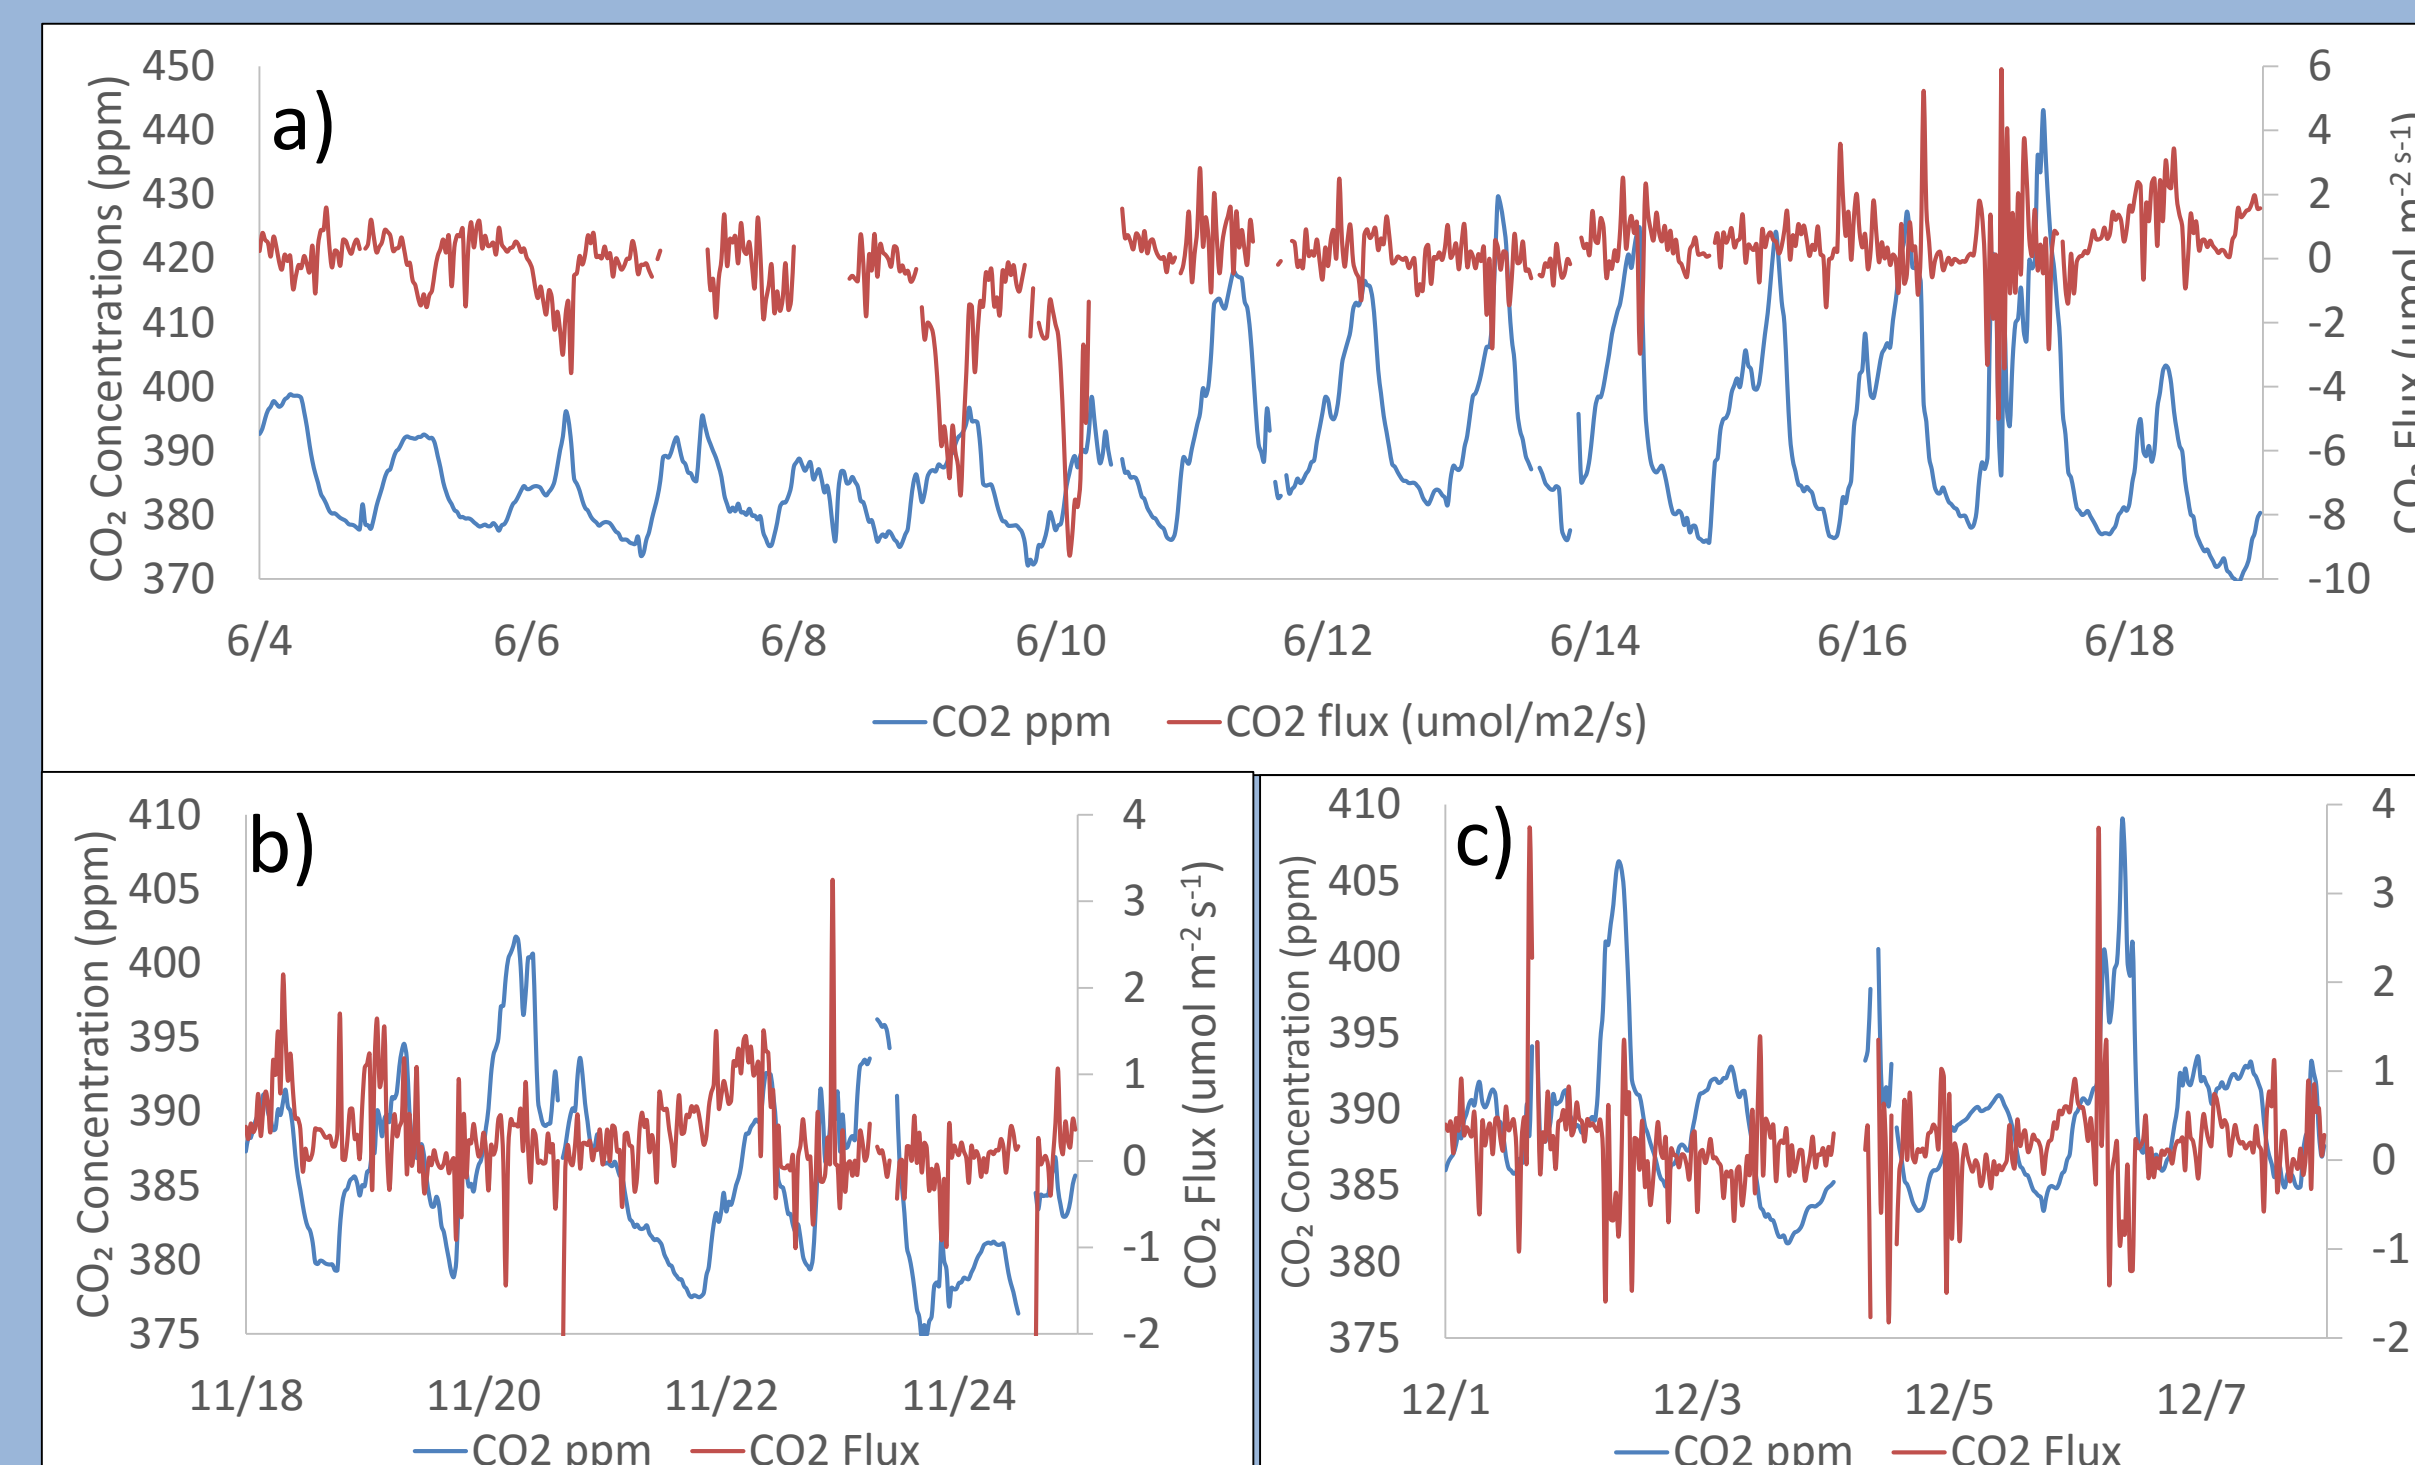

Figure 3: CO<sub>2</sub> concentration and CO<sub>2</sub> flux time series for a) June 4<sup>th</sup> to 18<sup>th</sup>, b) Nov. 18<sup>th</sup> to 24<sup>th</sup>, c) Dec. 1<sup>st</sup> to Dec 7<sup>th</sup>.

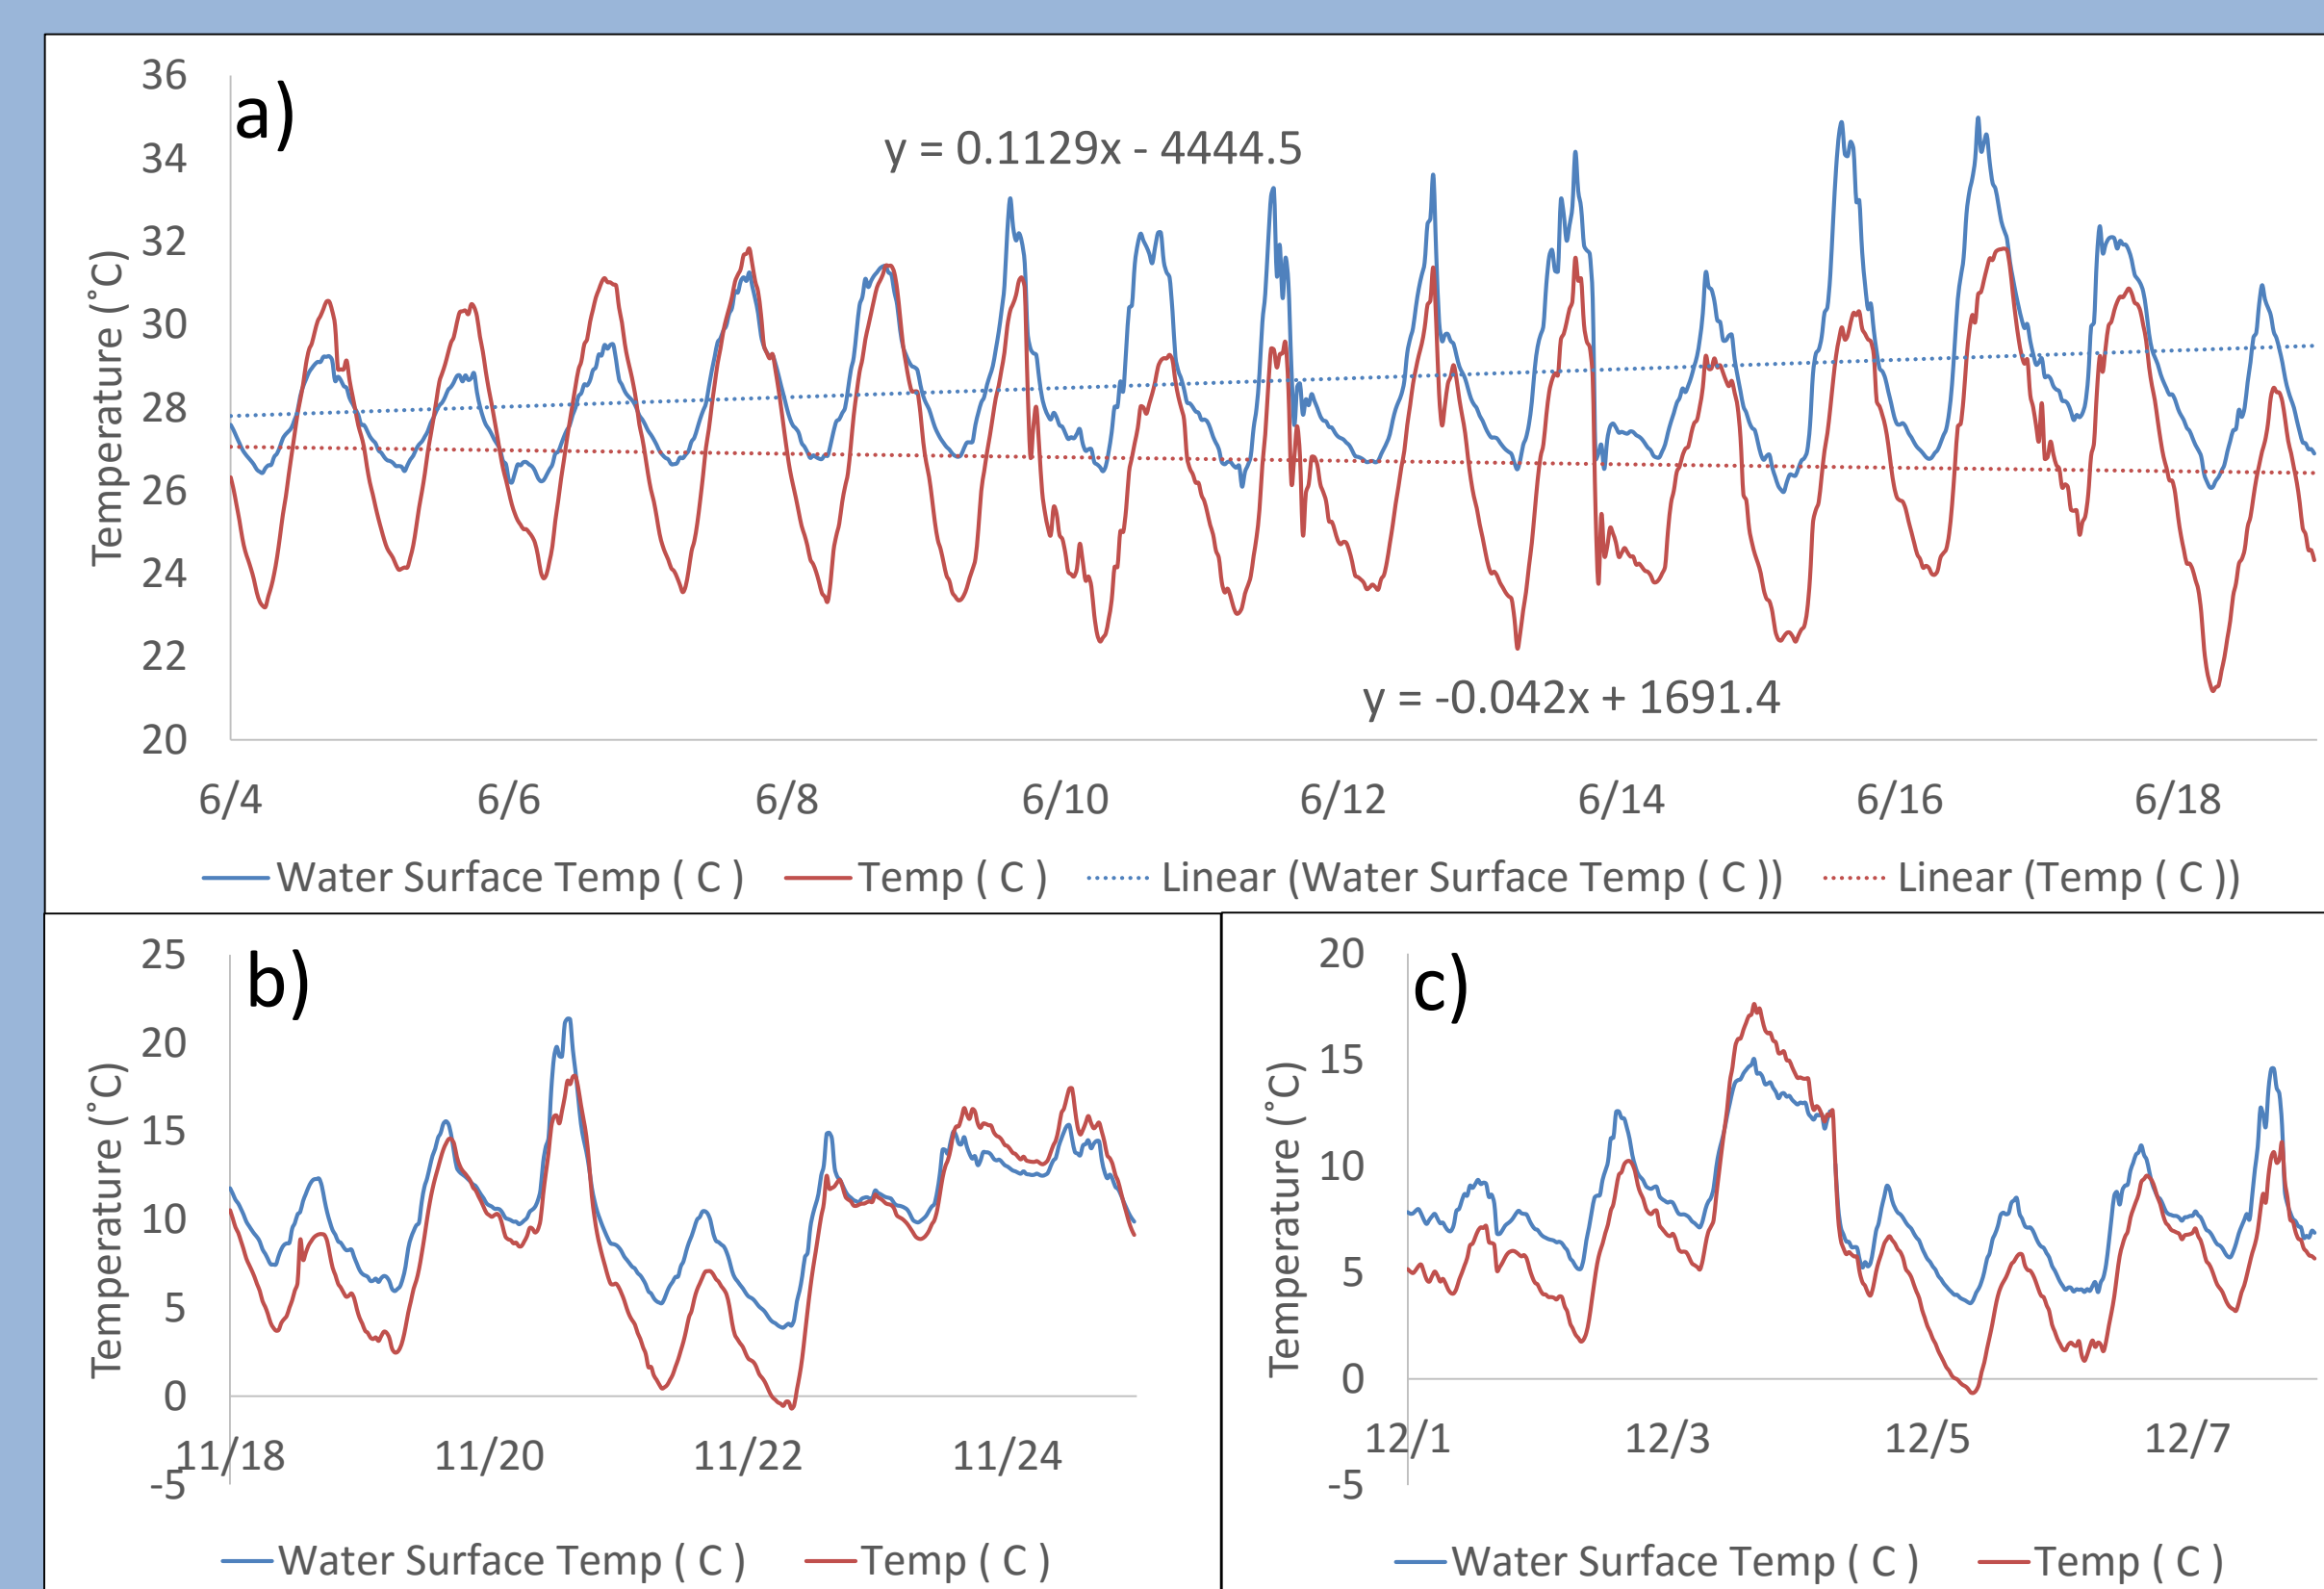

Figure 4: Air temperature and water surface temperature time series for a) June 4<sup>th</sup> to 18<sup>th</sup>, b) Nov. 18<sup>th</sup> to 24<sup>th</sup>, c) Dec 1<sup>st</sup> to Dec 7<sup>th</sup>

Figure 5: CO<sub>2</sub> concentration and net radiation time series for a) June 4<sup>th</sup> to June 18<sup>th</sup>, b) Nov. 18<sup>th</sup> to Nov 24<sup>th</sup>, c) Dec. 1<sup>st</sup> to Dec. 7<sup>th</sup>

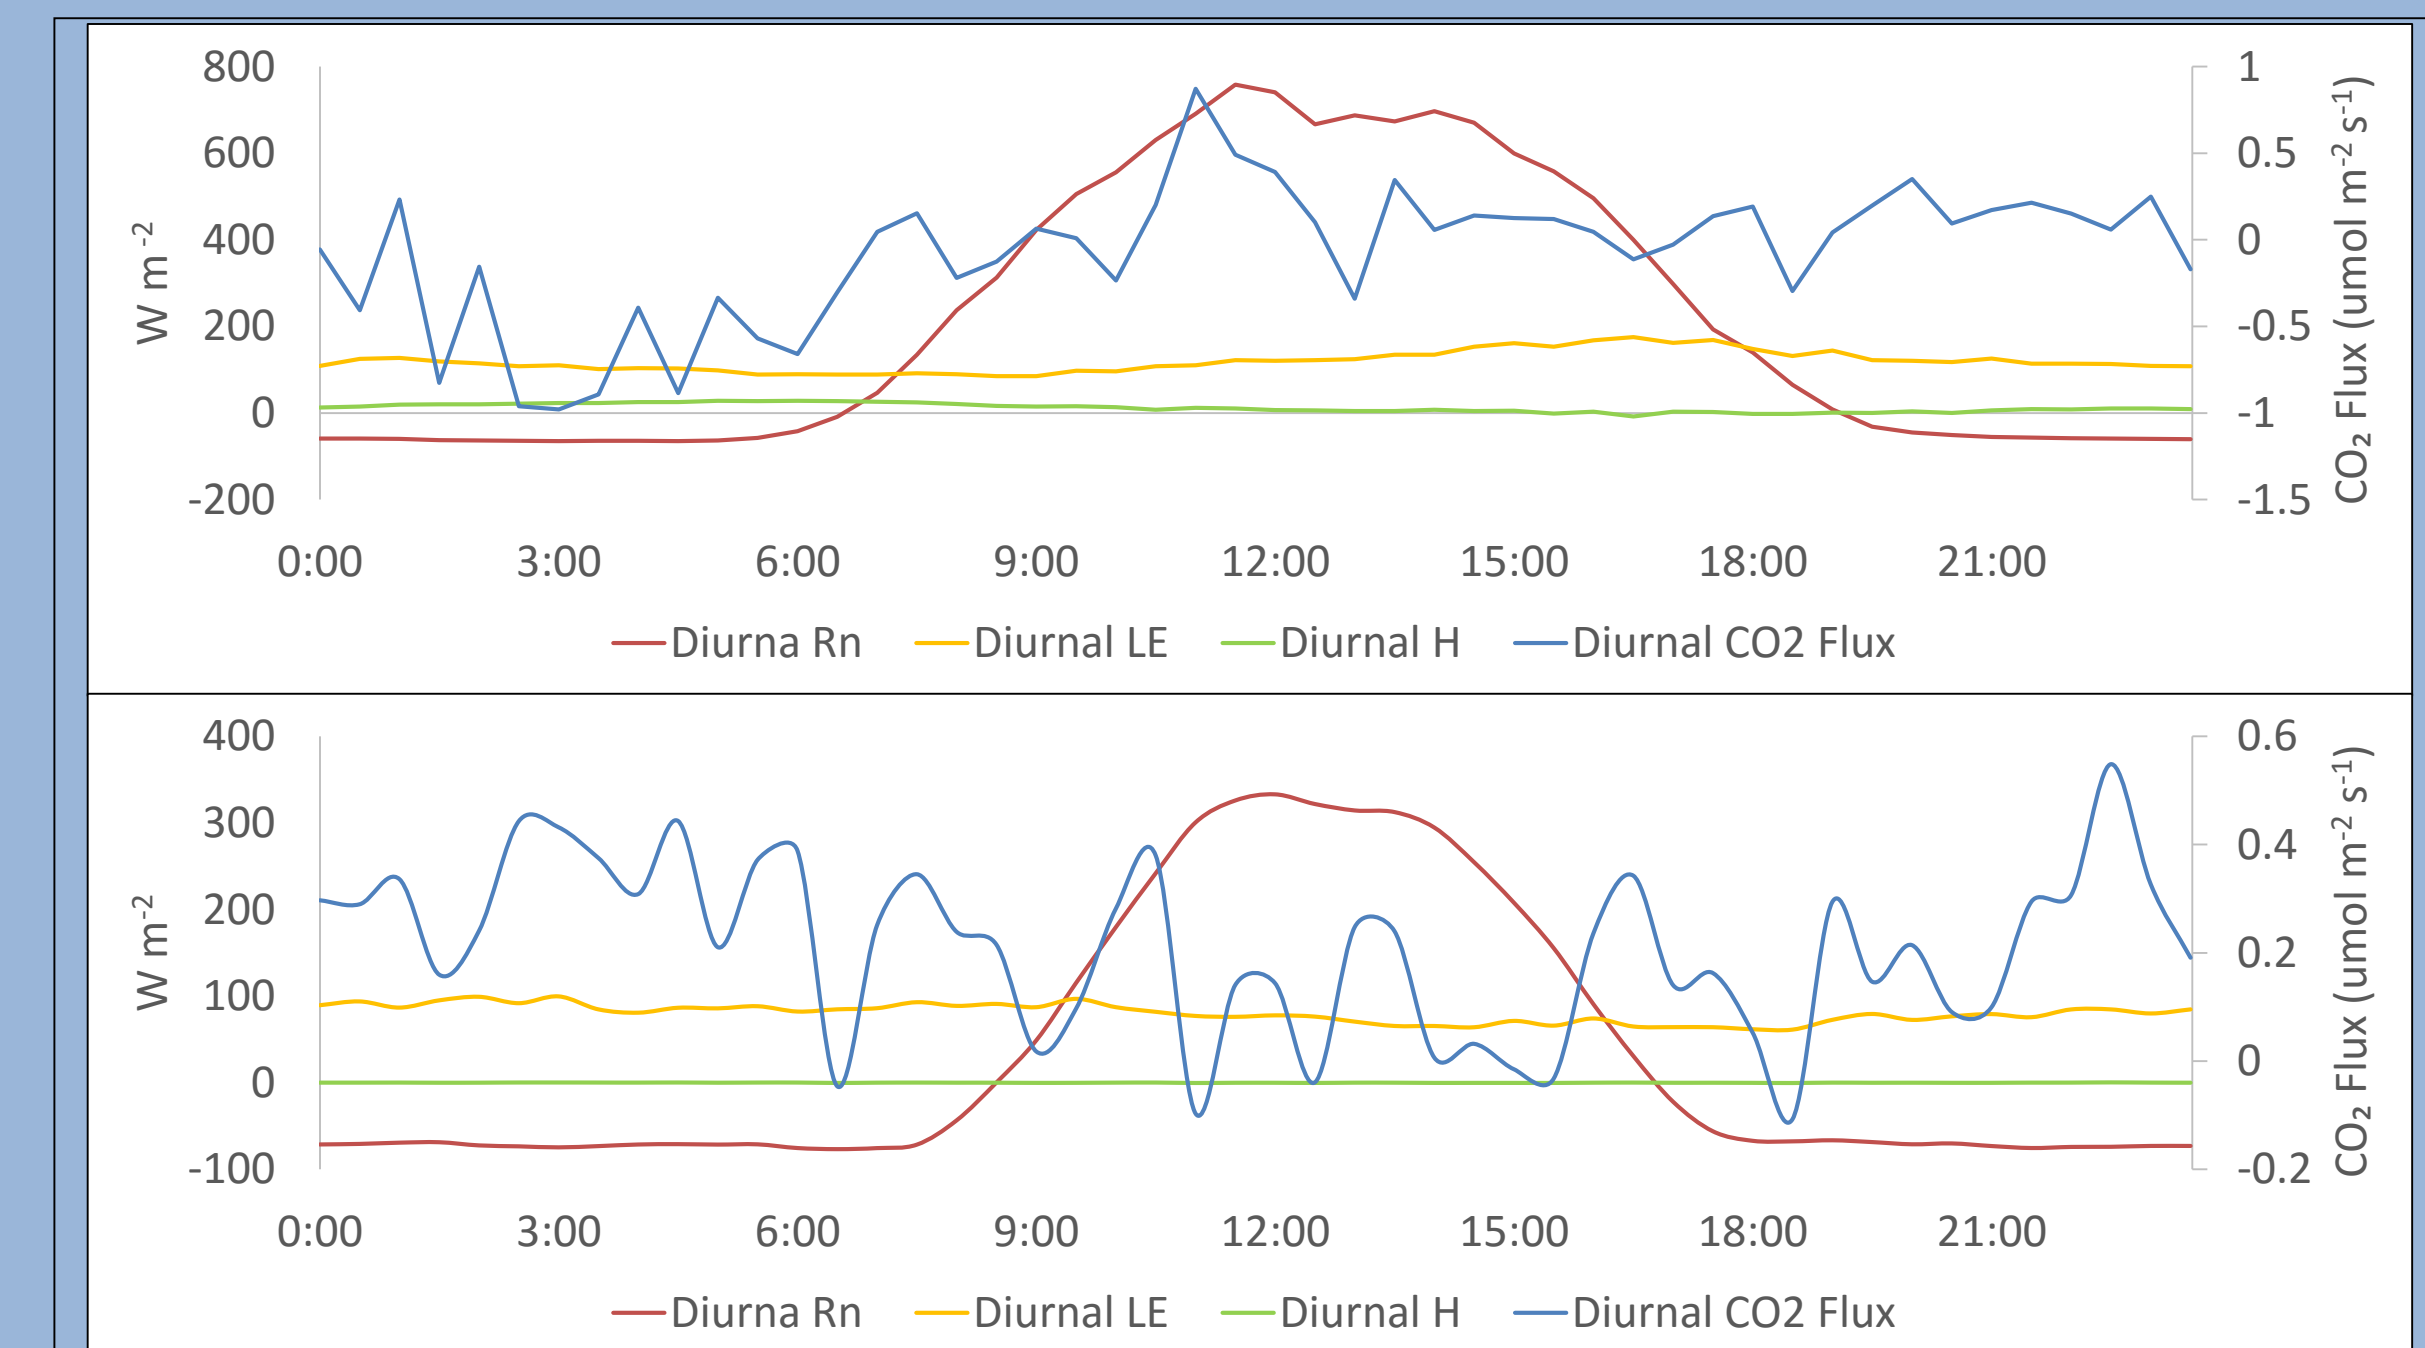

Figure 6: Diurnal analysis of net radiation (Rn), latent heat (LE), sensible heat (H), and CO<sub>2</sub> flux for a) June 4<sup>th</sup> to June 18<sup>th</sup>, b) Nov. 18<sup>th</sup> to 24<sup>th</sup> and Dec. 1<sup>st</sup> to 7<sup>th</sup>.

Figure 7: CO<sub>2</sub> concentration and wind speed for a) June 4<sup>th</sup> to 18<sup>th</sup>, b) Nov. 18<sup>th</sup> to 24<sup>th</sup>, and c) Dec. 1<sup>st</sup> to 7<sup>th</sup>.

## Conclusion

- An increase in CO<sub>2</sub> concentrations was observed with a negative flux from June 11<sup>th</sup> to the 17<sup>th</sup> and sporadically on Nov. 20<sup>th</sup> and 23<sup>rd</sup>, and on Dec. 2<sup>nd</sup>, 4<sup>th</sup>, and 6<sup>th</sup>.
- Average CO<sub>2</sub> concentrations were found in both June and November/December, with June having the higher average. This was likely due to a decrease in temperature during the fall.
- Periods of maximum CO<sub>2</sub> concentration typically occurred after the passage of cold fronts
- Calm winds and synoptic conditions allowed surface water to become warmer than the cold air above.
- The attributing factors of passing cold fronts with clear weather, increased net radiation, and water temperature were the cause of the flux in CO<sub>2</sub>.
